Lecture 12

Razvan C. Bunescu

School of Electrical Engineering and Computer Science

bunescu@ohio.edu
Scripting Languages: Python

• Designed by Guido van Rossum in the early 1990s.
• Current development done by the Python Software Foundation.

• Python facilitates multiple programming paradigms:
  – imperative programming.
  – object oriented programming.
  – functional programming.

⇒ multi-paradigm programming language.
Python: Important Features

• Python = object-oriented interpreted “scripting” language:
  – Object oriented:
    • modules, classes, exceptions.
    • dynamically typed, automatic garbage collection.
  – Interpreted, interactive:
    • rapid edit-test-debug cycle.
  – Extensible:
    • can add new functionality by writing modules in C/C++.
  – Standard library:
    • extensive, with hundreds of modules for various services such as regular expressions, TCP/IP sessions, etc.
Scripting Languages

- **Scripts vs. Programs:**
  - interpreted vs. compiled
  - one script = a program
  - many {*.c, *.h} files = a program

- **Higher-level “glue” language:**
  - glue together larger program/library components, potentially written in different programming languages.
    - orchestrate larger-grained computations.
    - vs. programming fine-grained computations.
  
  ```
  grep –i programming *.txt | grep –i python | wc -l
  ```
The Python Interpreter

Running the interpreter

[razvan@texas ~]$ python3
Python 3.4.0 (default, Apr 11 2014, 13:05:11)
[GCC 4.8.2] on linux
Type "help", "copyright", "credits" or "license" for more information.
>>>
The Python Interpreter: Help()

>>> help()

Welcome to Python 3.4! This is the interactive help utility.

If this is your first time using Python, you should definitely check out the tutorial on the Internet at http://docs.python.org/3.4/tutorial/.

Enter the name of any module, keyword, or topic to get help on writing Python programs and using Python modules. To quit this help utility and return to the interpreter, just type "quit".

To get a list of available modules, keywords, symbols, or topics, type "modules", "keywords", "symbols", or "topics". Each module also comes with a one-line summary of what it does; to list the modules whose name or summary contain a given string such as "spam", type "modules spam".

help>
The Python Interpreter: Keywords

help> keywords

Here is a list of the Python keywords. Enter any keyword to get more help.

False    def    if    raise
None      del    import    return
True      elif    in    try
and      else    is    while
as      except    lambda    with
assert      finally    nonlocal    yield
break    for    not
class    from    or
continue    global    pass
Lambda expressions (sometimes called lambda forms) have the same syntactic position as expressions. They are a shorthand to create anonymous functions; the expression "lambda arguments: expression" yields a function object. The unnamed object behaves like a function object defined with

```
def <lambda>(arguments):
    return expression
```

See section *Function definitions* for the syntax of parameter lists. Note that functions created with lambda expressions cannot contain statements or annotations.
The Python Interpreter: Modules

help> modules

**commands:**
execute shell commands via os.popen() and return status, output.

**compiler:**
package for parsing and compiling Python source code.

**gzip:**
functions that read and write gzipped files.

**HTMLParser:**
a parser for HTML and XHTML (defines a class HTMLParser).

**math:**
access to the mathematical functions defined by the C standard.

**exceptions:**
Python’s standard exception class hierarchy.
The Python Interpreter: Modules

```
help> modules

os:
    OS routines for Mac, NT, or Posix depending on what system we’re on.
re:
    support for regular expressions (RE).
string:
    a collection of string operations (most are no longer used).
sys:
    access to some objects used or maintained by the interpreter and to functions that interact strongly with the interpreter:
    `sys.argv`: command line arguments.
    `sys.stdin, sys.stdout, sys.stderr`: standard input, output, error file objects.
threading:
    thread modules emulating a subset of Java’s threading model.
```
The Python Interpreter: Integer Precision

>>> def fib(n):
    a, b, i = 0, 1, 0
    while i < n:
        a, b, i = b, a+b, i+1
    return a

>>> fib(10)
55
>>> fib(100)
354224848179261915075
>>> fib(1000)
4346655768693745643568852767504062580256466051737178040248172908953655541
4905189040387984007925516929592259308032263477520968962323987332247116164
996440906533187938298969649928516003704476137795166849228875
Built-in Types: Basic

- **integers**, with unlimited precision – `int()`.  
  - decimal, octal and hex literals.
- **floating point numbers**, implemented using double in C – `float()`.
- **complex numbers**, real and imaginary as double in C – `complex()`.
  - `10+5j, 1j`
  - `z.real, z.imag`
- **boolean values**, True and False – `bool()`.
  - False is: `None, False, 0, 0L, 0.0, 0j, '', (), [], {},`
  - user defined class defines methods `nonzero()` or `len()`.
- **strings** – `str()`, `class`, `function`, …
  - “Hello world”, ‘Hello world’
Built-in Types: Composite

- **lists:**
  - [], [1, 1, 2, 3], [1, “hello”, 2+5j]
- **tuples:**
  - (), (1,), (1, 1, 2, 3), (1, “hello, 2+5j)
- **dictionaries:**
  - {“john”: 12, “elaine”: 24}
- **sets:**
  - {1, 2, 3}
- **files**
Integers

>>> int
<class ‘int’>
>>> 1024
1024
>>> int(1024)
1024
>>> repr(1024)
‘1024’
>>> eval(‘1024’)
1024
>>> str(1111)
‘1111’
>>> int(‘1111’)
1111

>>> a = 100
>>> b = 200
>>> a + 1, b + 1  #this is a tuple
(101, 201)
>>> print(a, b + 1)
100 201
>>> int(3.6), abs(-10), 11%3, 11//3, 11/3, 2**3
(3, 10, 2, 3, 3.6666666666666665, 8)
>>> int(‘1110’,2), int(‘170’,8), int(‘40’,16)
(14, 120, 64)
>>> [170, 0170, 0x40] #this is a list
[170, 120, 64]
>>> float(8), 2**3, pow(2,3)
(8.0, 8, 8)
Booleans

>>> bool
<class 'bool'>
>>> [bool(0), bool(0.0), bool(0j), bool([]), bool(()), bool({}), bool(''), bool(None)]
[False, False, False, False, False, False, False, False]
>>> [bool(1), bool(1.0), bool(1j), bool([1]), bool((1,)), bool({1: 'one'}), bool('1')]
[True, True, True, True, True, True, True]
>>> str(True), repr(True)
('True', 'True')
>>> True and True, True and False, False and False
(True, False, False)
>>> True or True, True or False, False or False
(True, True, False)
>>> not True, not False
(False, True)

Lecture 12
Floating Point

>>> float
<class ‘float’>
>>> 3.14, 3.1400000000000001
(3.14, 3.14)
>>> repr(3.1400000000000001)
3.14
>>> 3.14/2, 3.14//2
(1.5, 1.0)
>>> import math
>>> math.pi, math.e
(3.1415926535897931, 2.7182818284590451)
>>> help(‘math’)

============= Python =============
>>> sum = 0.0
>>> for i in range(10):
. . . sum += 0.1
. . .
>>> sum
0.9999999999999999989

============= C++ =============
float sum = 0.0;
for (int i = 0; i < 10; i++)
 . . . sum += 0.1;
cout.precision(17);
cout << sum << endl;
⇒ 1.0000001192092896

http://docs.python.org/3/tutorial/introduction.html#numbers

Lecture 12
IEEE 754 Standard
Strings (Immutable)

• Immutable Sequences of Unicode Characters:

```python
g>>> str
<class 'str'>
g>>> s = "object oriented"
<ipython-input-1-92505c4f3fd2>:
15
1> len(s), s.find('ct'), s.split()
(15, 4, ['object', 'oriented'])
1> s[0], s[1], s[4:6], s[7:]
('o', 'b', 'ct', 'oriented')
1> s[7:100]
'oriented'
1> "functional {0} lang".format('programming')
'functional programming lang'
1> "object oriented " + "programming"
'object oriented programming'
1> 'orient' in 'object oriented', 'orient' in 'Object Oriented'
(True, False)
```

http://docs.python.org/3/tutorial/introduction.html#strings
List (Mutable)

```python
>>> []  # empty list
[]

>>> x = [3.14, "hello", True]
[3.14, 'hello', True]

>>> x + [10, [], len(x)]
[3.14, 'hello', True, 10, [], 3]

>>> x.append(0.0)

>>> x.reverse()

>>> x
[0.0, True, 'hello', 3.14]

>>> x.sort()

>>> x * 2
[0.0, True, 'hello', 3.14, 0.0, True, 'hello', 3.14]

>>> help('list')
```

Lecture 12
>>> tuple
<class 'tuple'>

>>> ()  # empty tuple
()

>>> (10)  # not a one element tuple!
10

>>> (10,)  # a one element tuple
(10,)

>>> (1, 2) + (3, 4)
(1, 2, 3, 4)

>>> (1, 2) * 2
(1, 2, 1, 2)

>>> x = (0, 1, 'x', 'y')

>>> x[0], x[1], x[:-1]
(0, 1, (0, 1, 'x'))

>>> y = (13, 20, -13, -5, 0)

>>> temp = list(y)

>>> (10)   # not a one element tuple!
10

>>> temp.sort()

>>> y = tuple(temp)

>>> y
(-13, -5, 0, 13, 20)

>>> help('tuple')
Set (Mutable) & Frozenset (Immutable)

```python
>>> set, frozenset
<class 'set'>, <class 'frozenset'>

>>> set()  # empty set
set()

>>> type(set())
<class 'set'>

>>> {}  # not an empty set!
{}

>>> type({})
<class 'dict'>

>>> s = {1, 3, 3, 2}
>>> s
{1, 2, 3}

>>> frozenset({1, 3, 3, 2})
frozenset({1, 2, 3})

>>> 3 in s, 4 in s
(True, False)

>>> s = set('yellow')
>>> t = set('hello')

>>> s
{'e', 'o', 'l', 'w', 'y'}

>>> t
{'h', 'e', 'l', 'o'}

>>> s – t, s | t
({'w', 'y'}, {'h', 'e', 'o', 'l', 'w', 'y'})

>>> s & t, s ^ t
({'e', 'l', 'o'}, {'h', 'w', 'y'})

>>> {1, 3} <= {1, 2, 3, 2}
True

>>> help(set) >>> help(frozenset)
```
Mutable Operations on Sets

```python
>>> s = set(['abba', 'dada', 'lola', 'bama'])
>>> s
{'abba', 'bama', 'dada', 'lola'}
>>> s |= {'bama', 'lily'}
>>> s
{'abba', 'bama', 'dada', 'lily', 'lola'}
>>> s -= {'lola', 'abba', 'mama'}
>>> s
{'bama', 'dada', 'lily'}
>>> s &= {'lily', 'dodo', 'bama'}
>>> s
{'bama', 'lily'}
>>> s = {1}
>>> s
TypeError: unhashable type: 'list'
```

How can we prove the actual set object changes and not a new one is created?

Hint: are `s -= t` and `s = s - t` equivalent for sets? How about strings?
Dictionaries (Mutable)

```python
>>> dict
<class 'dict'>
>>> {}
# empty dictionary
{}
>>> d = {'john':23, 'alex':25, 'bill':99}
>>> d['alex']
25
>>> d['alex'] = 26
>>> del d['john']
>>> d['tammy'] = 35
>>> d
{'alex':26, 'bill':99, 'tammy':35}
>>> d.items()
# this is a view
dict_items[('alex',26), ('bill',99), ('tammy',35)]
>>> d.keys()
# this is a view
dict_keys['alex', 'bill', 'tammy']
>>> d.values()
# this is a view
dict_values[26, 99, 35]
>>> for x, y in d.items():
    ... print (x, y)
    ‘alex’ 26
    ‘bill’ 99
    ‘tammy’ 35
>>> for key in d:
    ... print(key, end = ‘ ‘)
    ‘alex’ ‘bill’ ‘tammy’
>>> d.keys() | ['alex', 'john']
# set ops.
dict_keys[‘alex’, ‘bill’, ‘tammy’, ‘mary’]
```
Dictionaries (Mutable)

>>> dict
<class 'dict'>

>>> d.items()  # this is a view
dict_items[('alex', 26), ('bill', 99), ('tammy', 35)]

>>> {}  # empty dictionary
{}
dict_keys[

>>> d = {'john': 23, 'alex': 25, 'bill': 99}

>>> d.values()  # this is a view
>>> d['alex']
dict_values[26, 99, 35]

25

>>> for x, y in d.items():

>>> d['alex'] = 26

>>> … print (x, y)

>>> del d['john']

>>> d['tammy'] = 35

>>> d
dict_keys[

>>> d['mary'] = 10

>>> for key in d:

>>> d.keys() | ['alex', 'john']  # set ops.

Immutable types are hashable, mutable types are not:

>>> d = dict(abba=1, dada=2)

>>> d[frozenset({1, 2, 3})] = 3

>>> d[1, 2, 3] = 4

>>> d
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: unhashable type: 'set'
Files

>>> file
<type ‘file’>
>>> output = open(‘/tmp/output.txt’, ‘w’)  # open tmp file for writing
>>> input = open(‘/etc/passwd’, ‘r’)  # open Unix passwd file for reading
>>> s = input.read()  # read entire file into string s
>>> line = input.readline()  # read next line
>>> lines = input.readlines()  # read entire file into list of line strings
>>> output.write(s)  # write string S into output file
>>> output.write(lines)  # write all lines in ‘lines’
>>> output.close()
>>> input.close()

>>> from urllib import urlopen
>>> html = urlopen(‘http://www.ohio.edu’)  # open html file for reading
>>> lines = [line[:-1] for line in html.readlines()]
Statements & Functions

- Assignment Statements
- Compound Statements
- Control Flow:
  - Conditionals
  - Loops
- Functions:
  - Defining Functions
  - Lambda Expressions
  - Documentation Strings
  - Generator Functions
Assignment Forms

- **Basic form:**
  - \( x = 1 \)
  - \( y = 'John' \)
- **Tuple positional assignment:**
  - \( x, y = 1, 'John' \)
  - \( x == 1, b == 'John' \Rightarrow (True, True) \)
- **List positional assignment:**
  - \([x, y] = [1, 'John']\)
- **Multiple assignment:**
  - \( x = y = 10 \)
Compound Statements

- Python does not use block markers (e.g. ‘begin .. end’ or ‘{ … }’) to denote a compound statements.
  - Need to indent statements at the same level in order to place them in the same block.
  - Can be annoying, until you get used to it; intelligent editors can help.
  - Example:
    ```python
    if n == 0:
        return 1
    else:
        return n * fact(n - 1)
    ```
Conditional Statements

```python
if <bool_expr_1>:
    <block_1>
elif <bool_expr_2>:
    <block_2>
    ...
else:
    <block_n>
```

- There can be zero or more `elif` branches.
- The `else` branch is optional.
- "Elif" is short for "else if" and helps in reducing indentation.
name = 'John'
...
if name == 'Mary':
    sex = 'female'
elif name == 'John':
    sex = 'male'
elif name == 'Alex':
    sex = 'unisex'
elif name == 'Paris':
    sex = 'unisex'
else:
    sex = 'unknown'
Conditional Statements

• There is no C-like ‘switch’ statement in Python.
• Same behavior can be achieved using:
  – if ... elif ... elif sequences.
  – dictionaries:

    ```python
    name = 'John'
    dict = {'Mary':'female', 'John': 'male', 'Alex':'unisex', 'Paris':'unisex'}
    if name in dict:
        print(dict[name])
    else:
        print('unknown')
    ```
While Loops

\[
x = 'university'
while x:
    print(x, end = ' ')
    x = x[1:]
\]

\[
a, b = 1, 1
while b <= 23:
    print(a, end = ' ')
    a, b = b, a + b
\]
For Loops

```python
sum = 0
for x in [1, 2, 3, 4]
    sum += x
print(sum)

D = {1:'a', 2:'b', 3:'c', 4:'d'}
for x, y in D.items():
    print(x, y)
```
Names and Scopes

• Static scoping rules.
  – if \( x \) is a variable name that is only read, its variable is found in the closest enclosing scope that contains a defining write.
  – a variable \( x \) that is written is assumed to be local, unless it is explicitly imported.
  – use `global` and `nonlocal` keywords to override these rules.

• Example:
Functions

def mul(x, y):
    return x * y

mul(2, 5) => ?
mul(math.pi, 2.0) => ?
mul([1, 2, 3], 2) => ?
mul(('a', 'b'), 3) => ?
mul('ou', 5) => ?
def f(a, b, c): print(a, b, c)
f(1, 2, 3) => 1 2 3
f(b = 1, c = 2, a = 3) => 3 1 2

def f(*args): print(args)
f(“one argument”) => (‘one argument’)
f(1, 2, 3) => (1, 2, 3)

def f(**args): print args
f(a=2, b=4, c=8) => {‘a’:2, ‘b’:4, ‘c’:8}
Lambda Expressions

- **Scheme:**
  > (define (make-adder (num)
  >    (lambda (x)
  >      (+ x num)))

- **Python:**
  >>> def make_adder(num):
  ...    return lambda x: x + num
  ...
  >>> f = make_adder(10)
  >>> f(9)
  19
Lambda Expressions

>>> formula = lambda x, y: x * x + x * y + y * y
>>> formula
<function <lambda> at 0x2b3f213ac230>
>>> apply(formula, (2,3))
19
>>> list(map(lambda x: 2 * x, [1, 2, 3]))
[2, 4, 6]
>>> list(filter(lambda x: x > 0, [1, -1, 2, -2, 3, 4, -3, -4]))
[1, 2, 3, 4]
>>> from functools import reduce
>>> reduce(lambda x, y: x * y, [1, 2, 3, 4, 5])
120
>>> def fact(n): return reduce (lambda x, y: x * y, range(1, n+1))
>>> fact(5)
120
Iterators

• An iterator is an object representing a stream of data:
  – to get the next element in the stream:
    • call `__next__()` method.
    • pass the iterator to the built-in function `next()`.
  – to create an iterator:
    • call `iter(collection)`.
    • some functions create iterators/iterables instead of collections:
      – `map()`, `filter()`, `zip()`, ...
      – `range()`, `dict.keys()`, `dict.items()`, ...
      – why create iterators/iterables instead of collections?

• Examples:
for x in \texttt{range}(5):
    print(x)

Internally, this is implemented as:

\begin{verbatim}
it = iter(range(5))
while True:
    try:
        x = next(it)
        print(x)
    except StopIteration:
        break
\end{verbatim}
A Convenient Shortcut to Building Iterators: Generator Functions/Expressions

def squares(n):
    for i in range(n):
        yield i*i

>>> for i in squares(5):
...    print(i, end = ' ')
0 1 4 9 16

>>> s = squares(5)

>>> next(s) => 0
>>> next(s) => 1
>>> next(s) => 4

Equivalent generator expression:

>>> (i * i for i in range(n))
def fib():  # generate Fibonacci series
    a, b = 0, 1
    while 1:
        yield b
        a, b = b, a+b

>>> it = fib()
>>> next(it) => 1
>>> next(it) => 1
>>> next(it) => 2
List/Set/Dict Comprehensions

- Mapping operations over sequences is a very common task in Python coding: ⇒ introduce a new language feature called *list comprehensions*.

```python
>>> [x**2 for x in range(5)]
[0, 1, 4, 9, 25]

>>> [x for x in range(5) if x % 2 == 0]
[0, 2, 4]

>>> [x+y for x in [1, 2, 3] for y in [-1,0,1]]
[0,1,2,1,2,3,2,3,4]

>>> [(x,y) for x in range(5) if x%2 == 0 for y in range(5) if y%2==1]
[(0,1), (0,3), (2,1), (2,3), (4,1), (4,3)]
```
List/Set/Dict Comprehensions

```
[expression for target_1 in iterable_1 [if condition]
 for target_2 in iterable_2 [if condition]
 ... 
 for target_n in iterable_n [if condition] ]
```

```python
>>> [line[:-1] for line in open('myfile')]
>>> {x for x in 'ohio' if x not in 'hawaii'}
>>> {x:2*x for x in 'ohio'}
>>> {x:y for x in [1, 2] for y in [3, 4]}
```
Errors & Exceptions

- **Syntax errors:**
  ```python
  while True print 'True'
  File "<stdin>", line 1
      while True print 'True'
      ^
  SyntaxError: invalid syntax
  ```

- **Exceptions: errors detected during execution:**
  ```python
  1 / 0
  Traceback (most recent call last):
    File "<stdin>", line 1, in ?
  ZeroDivisionError: integer division or modulo by zero
  ```
Handling Exceptions

for arg in sys.argv[1:]:
    try:
        f = open(arg, 'r')
    except IOError:
        print('cannot open', arg)
    else:
        print(arg, 'has', len(f.readlines()), 'lines')
    f.close()
Modules

- Python has a way to put definitions in a file and use them in a script or in an interactive instance of the interpreter.
- A **module** is a file containing Python definitions and statements.
- The file name is the module name with the suffix `.py` appended.
- Within a module, the module's name (as a string) is available as the value of the global variable `__name__`
# Fibonacci numbers module

def fib(n):
    # write Fibonacci series up to n
    a, b = 0, 1
    while b < n:
        print b,
        a, b = b, a+b

>>> import fibo
>>> fibo.fib(100)
1 1 2 3 5 8 13 21 34 55 89
